EVALUATION KIT MAXM AVAILABLE 1.25Gbps/2.5Gbps, +3V to +5.5V, Low-Noise Transimpedance Preamplifiers for LANs

General Description

The MAX3266 is a transimpedance preamplifier for 1.25Gbps local area network (LAN) fiber optic receivers. The circuit features 200nA input-referred noise, 920MHz bandwidth, and 1mA input overload.

The MAX3267 provides a pin-for-pin compatible solution for communications up to 2.5Gbps. It features 500nA input-referred noise, 1.9GHz bandwidth, and 1mA input overload.

Both devices operate from a +3.0V to +5.5V single supply and require no compensation capacitor. They also include a space-saving filter connection that provides positive bias for the photodiode through a 1.5k Ω resistor to VCC. These features allow easy assembly into a TO-46 or TO-56 header with a photodiode.

The 1.25Gbps MAX3266 has a typical optical dynamic range of -24dBm to 0dBm in a shortwave (850nm) configuration or -27dBm to -3dBm in a longwave (1300nm) configuration. The 2.5Gbps MAX3267 has a typical optical dynamic range of -21dBm to 0dBm in a shortwave configuration or -24dBm to -3dBm in a longwave configuration.

Applications

Gigabit Ethernet

1Gbps to 2.5Gbps Optical Receivers

Fibre Channel

- ♦ **200nA Input-Referred Noise (MAX3266) 500nA Input-Referred Noise (MAX3267)**
- ♦ **920MHz Bandwidth (MAX3266) 1900MHz Bandwidth (MAX3267)**
- ♦ **1mA Input Overload**
- ♦ **+3.0V to +5.5V Single-Supply Voltage**

Ordering Information

*Dice are designed to operate over a -40°C to $+140^{\circ}$ C junction temperature (Ti) range, but are tested and guaranteed at $T_A = +25^{\circ}C$.

ABSOLUTE MAXIMUM RATINGS

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ELECTRICAL CHARACTERISTICS—MAX3266C/MAX3267C

(V_{CC} = +3.0V to +5.5V, T_A = 0°C to +70°C, 100 Ω load between OUT+ and OUT-. Typical values are at T_A = +25°C, V_{CC} = 3.3V, source capacitance = $0.85pF$, unless otherwise noted.) (Note 1)

ELECTRICAL CHARACTERISTICS—MAX3267E

(V_{CC} = +3.0V to +5.5V, T_A = -40°C to +85°C, 100 Ω load between OUT+ and OUT-. Typical values are at T_A = +25°C, V_{CC} = 3.3V, source capacitance = $0.85pF$, unless otherwise noted.) (Note 1)

Note 1: Source Capacitance represents the total capacitance at the IN pin during characterization of noise and bandwidth parameters. Figure 1 shows the typical source capacitance vs. reverse voltage for the photodiode used during characterization of TO-56 header packages. Noise and bandwidth will be affected by the source capacitance. See the Typical Operating Characteristics for more information.

Note 2: Input-Referred Noise is calculated as RMS Output Noise / (Gain at f = 10MHz). Noise Density is (Input-Referred Noise) / √bandwidth. No external filters are used for the noise measurements.

Note 3: Deterministic Jitter is measured with the K28.5 pattern applied to the input [00111110101100000101].

Pin Description

MAXIM

MAX3266/MAX3267

MAX3266/MAX3267

Detailed Description

The MAX3266 is a transimpedance amplifier designed for 1.25Gbps fiber optic applications. Figure 2 is a functional diagram of the MAX3266, which comprises a transimpedance amplifier, a voltage amplifier, an output buffer, an output filter, and a DC cancellation circuit.

The MAX3267, a transimpedance amplifier designed for 2.5Gbps fiber optic applications, shares similar architecture with the MAX3266.

Figure 1. Typical Photodiode Capacitance vs. Bias Voltage

Transimpedance Amplifier

The signal current at the input flows into the summing node of a high-gain amplifier. Shunt feedback through RF converts this current to a voltage with gain of approximately 2.2kΩ (1.0kΩ for MAX3267). Schottky diodes clamp the output voltage for large input currents, as shown in Figure 3.

Voltage Amplifier

The voltage amplifier converts single-ended signals to differential signals and introduces a voltage gain.

Output Buffer

The output buffer provides a reverse-terminated voltage output. The buffer is designed to drive a 100Ω differential load between OUT+ and OUT-. The output current is divided between internal 50Ω load resistors and the external load resistor. In the typical operating circuit, this creates a voltage-divider with gain of 1/2. The MAX3266 can also be terminated with higher output impedances, which increases gain and output voltage swing.

For optimum supply-noise rejection, the MAX3266 should be terminated with a differential load. If a singleended output is required, the unused output should be similarly terminated. The MAX3266 will not drive a DCcoupled, 50Ω grounded load.

Figure 2. MAX3266 Functional Diagram

Output Filter

The MAX3266 includes a one-pole lowpass filter that limits the circuit bandwidth and improves noise performance.

DC Cancellation Circuit

The DC cancellation circuit uses low-frequency feedback to remove the DC component of the input signal (Figure 4). This feature centers the input signal within the transimpedance amplifier's linear range, thereby reducing pulse-width distortion on large input signals.

The DC cancellation circuit is internally compensated and therefore does not require external capacitors. This circuit minimizes pulse-width distortion for data sequences that exhibit a 50% duty cycle. A duty cycle significantly different from 50% will cause the MAX3266 to generate pulse-width distortion.

DC cancellation current is drawn from the input and creates noise. For low-level signals with little or no DC component, this is not a problem. Amplifier noise will increase for signals with significant DC component (see Typical Operating Characteristics).

Applications Information

Optical Power Relations

Many of the MAX3266 specifications relate to the input signal amplitude. When working with fiber optic receivers, the input is usually expressed in terms of average optical power and extinction ratio. Figure 5 shows relations that are helpful for converting optical power to input signal when designing with the MAX3266.

Optical power relations are shown in Table 1; the definitions are true if the average duty cycle of the input data is 50%.

Optical Sensitivity Calculation

The input-referred RMS noise current (IN) of the MAX3266 generally determines the receiver sensitivity. To obtain a system bit error rate (BER) of 1E-12, the SNR ratio must always exceed 14.1. The input sensitivity, expressed in average power, can be estimated as:

$$
\text{Sensitivity} = 10 \log \left(\frac{14.1 \, \text{I}_{\text{N}} \, \left(\text{r}_{\text{e}} \; + \; 1 \right)}{2 \rho \left(\text{r}_{\text{e}} \; - \; 1 \right)} 1000 \right) \, \text{dBm}
$$

Where ρ is the photodiode responsivity in A/W.

Input Optical Overload

The overload is the largest input that the MAX3266 accepts while meeting specifications. The optical overload can be estimated in terms of average power with the following equation:

Overload =
$$
10 \log \left(\frac{1 mA}{2p} 1000 \right)
$$
 dBm

MAX3266/MAX3267 NAX3266/MAX3267

Figure 5. Optical Power Relations

Table 1. Optical Power Relations

Optical Linear Range

The MAX3266 has high gain, which limits the output when the input signal exceeds 30µAp-p (40µAp-p for MAX3267). The MAX3266 operates in a linear range for inputs not exceeding:

Linear Range =
$$
10\log\left(\frac{30\mu A(r_e + 1)}{2\rho(r_e - 1)}1000\right)
$$
 dBm

Layout Considerations

Use good high-frequency design and layout techniques. The use of a multilayer circuit board with separate ground and power planes is recommended. Connect the GND pins to the ground plane with the shortest possible traces.

Noise performance and bandwidth will be adversely affected by capacitance at the IN pin. Minimize capacitance on this pin and select a low-capacitance photodiode. Assembling the MAX3266 in die form using chip and wire technology provides the best possible performance. Figure 6 shows a suggested layout for a TO header.

The SO package version of the MAX3266 is offered as an easy way to characterize the circuit and become familiar with the circuit's operation, but it does not offer optimum performance. When using the SO version of the MAX3266, the package capacitance adds approximately 0.3pF at the input. The PC board between the MAX3266 input and the photodiode also adds parasitic capacitance. Keep the input line short, and remove power and ground planes beneath it.

Photodiode Filter

Supply voltage noise at the cathode of the photodiode produces a current $I = CPD \Delta V/\Delta t$, which reduces the receiver sensitivity (C_{PD} is the photodiode capacitance.) The filter resistor of the MAX3266, combined with an external capacitor, can be used to reduce this noise (see the Typical Application Circuit). Current generated by supply noise voltage is divided between CFILTER and CPD. The input noise current due to supply noise is (assuming the filter capacitor is much larger than the photodiode capacitance):

$$
I_{NOISE} = (V_{NOISE})(CPD) / (RFI_LTER)(CFI_LTER)
$$

If the amount of tolerable noise is known, the filter capacitor can be easily selected:

$$
CFILTER = (VNOISE)(CPD) / (RFILTER)(INOISE)
$$

For example, with maximum noise voltage = 100mVp-p , $CPD = 0.85pF$, RFILTER = 1.5k Ω , and INOISE selected to be 100nA (1/2 of the MAX3266's input noise):

```
CFILTER = (100mV)(0.85pF) / (1500Ω)(100nA) = 570pF
```
Wire Bonding

For high current density and reliable operation, the MAX3266 uses gold metalization. Connections to the die should be made with gold wire only, using ballbonding techniques. Wedge bonding is not recommended. Die thickness is typically 15mils (0.375mm).
