GENERAL DESCRIPTION

The AD5241/AD5242 provide a single-/dual-channel, 256 position, digitally controlled variable resistor (VR) device. These devices perform the same electronic adjustment function as a potentiometer, trimmer, or variable resistor. Each VR offers a completely programmable value of resistance between the A Terminal and the wiper, or the B Terminal and the wiper. For AD5242, the fixed A-to-B terminal resistance of 10 kΩ, 100 kΩ, or 1 MΩ has a 1% channel-to-channel matching tolerance. The nominal temperature coefficient of both parts is 30 ppm/ C .

Wiper position programming defaults to midscale at system power ON. Once powered, the VR wiper position is programmed by an I²C compatible 2-wire serial data interface. Both parts have available two extra programmable logic outputs that enable users to drive digital loads, logic gates, LED drivers, and analog switches in their system.

The AD5241/AD5242 are available in surface-mount (SOIC-14/- 16) packages and, for ultracompact solutions, TSSOP-14/-16 packages. All parts are guaranteed to operate over the extended temperature range of –40°C to +105°C. For 3-wire, SPI compatible interface applications, please refer to AD5200, AD5201, AD5203, AD5204, AD5206, AD5231*, AD5232*, AD5235*, AD7376, AD8400, AD8402, and AD8403 products.

*Nonvolatile digital potentiometer I ²C is a registered trademark of Philips Corporation.

REV. B

10 k Ω , 100 k Ω , 1 M Ω VERSION otherwise noted.) **otherwise noted.)**

NOTES

¹Typicals represent average readings at 25 $\rm{^{\circ}C},$ V_{DD} = 5 V.

 2 Resistor position nonlinearity error R-INL is the deviation from an ideal value measured between the maximum resistance and the minimum resistance wiper positions. R-DNL measures the relative step change from ideal between successive tap positions. Parts are guaranteed monotonic. See Test Circuits.

³INL and DNL are measured at V_W with the RDAC configured as a potentiometer divider similar to a voltage output D/A converter. V_A = V_{DD} and V_B = 0 V.

DNL specification limits of ±1 LSB maximum are guaranteed monotonic operating conditions. See Figure 10.

⁴Resistor terminals A, B, W have no limitations on polarity with respect to each other.

⁵Guaranteed by design and not subject to production test.

 ${}^{6}P_{\text{DISS}}$ is calculated from (I_{DD} × V_{DD}). CMOS logic level inputs result in minimum power dissipation.

⁷Bandwidth, noise, and settling time are dependent on the terminal resistance value chosen. The lowest R value results in the fastest settling time and highest bandwidth. The highest R value results in the minimum overall power consumption.

⁸All dynamic characteristics use $V_{DD} = 5 V$.

 9 See timing diagram for location of measured values.

Specifications subject to change without notice.

ABSOLUTE MAXIMUM RATINGS*

 $(T_A = 25\degree C,$ unless otherwise noted.)

*Max current increases at lower resistance and different packages.

ORDERING GUIDE

NOTES

¹The AD5241/AD5242 die size is 69 mil × 78 mil, 5,382 sq. mil. Contains 386 transistors for each channel. Patent Number 5495245 applies. ²TSSOP packaged units are only available in 1,000-piece quantity Tape and Reel.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD5241/AD5242 feature proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

AD5242 PIN CONFIGURATION

AD5242 PIN FUNCTION DESCRIPTIONS

Figure 1. Detail Timing Diagram

Data of AD5241/AD5242 is accepted from the $I²C$ bus in the following serial format:

where:

S = Start Condition

P = Stop Condition

A = Acknowledge

X = Don't Care

AD1, AD0 = Package pin programmable address bits. Must be matched with the logic states at Pins AD1 and AD0.

 R/\overline{W} = Read Enable at High and output to SDA. Write Enable at Low.

 \overline{A}/B = RDAC subaddress select. '0' for RDAC1 and '1' for RDAC2.

RS = Midscale reset, active high.

SD = Shutdown in active high. Same as SHDN except inverse logic.

 O_1 , O_2 = Output logic pin latched values.

D7, D6, D5, D4, D3, D2, D1, D0 = Data Bits.

OPERATION

The AD5241/AD5242 provide a single-/dual-channel, 256 position digitally controlled variable resistor (VR) device. The terms VR, RDAC, and programmable resistor are commonly used interchangeably to refer to digital potentiometer.

To program the VR settings, refer to the Digital Interface section. Both parts have an internal power ON preset that places the wiper in midscale during power-on, which simplifies the fault condition recovery at power-up. In addition, the shutdown SHDN Pin of AD5241/AD5242 places the RDAC in an almost zero power consumption state where Terminal A is open circuited and Wiper W is connected to Terminal B, resulting in only leakage current being consumed in the VR structure. During shutdown, the VR latch contents are maintained when the RDAC is inactive. When the part is returned from shutdown, the stored VR setting will be applied to the RDAC.

Figure 4. Equivalent RDAC Circuit

PROGRAMMING THE VARIABLE RESISTOR Rheostat Operation

The nominal resistance of the RDAC between Terminals A and B is available in 10 k Ω , 100 k Ω , and 1 M Ω . The final two or three digits of the part number determine the nominal resistance value, e.g., $10 kΩ = 10$; $100 kΩ = 100$; $1 MΩ = 1 M$. The nominal resistance (R_{AB}) of the VR has 256 contact points accessed by the Wiper Terminal, plus the B Terminal contact. The 8-bit data in the RDAC latch is decoded to select one of the 256 possible settings. Assume a $10 \text{ k}\Omega$ part is used; the wiper's first connection starts at the B Terminal for data 00_H. Since there is a 60 Ω wiper contact resistance, such connection yields a minimum of 60 Ω resistance between Terminals W and B. The second connection is the first tap point that corresponds to 99 Ω ($R_{WB} = R_{AB}/256 + R_W = 39 + 60$) for data 01_H . The third connection is the next tap point representing 138 Ω (39 × 2 + 60) for data 02_H, and so on. Each LSB data value increase moves the wiper up the resistor ladder until the last tap point is reached at 10021 Ω [R_{AB} – 1 LSB + R_W]. Figure 4 shows a simplified diagram of the equivalent RDAC circuit where the last resistor string will not be accessed; therefore, there is 1 LSB less of the nominal resistance at full scale in addition to the wiper resistance.

The general equation determining the digitally programmed resistance between W and B is:

$$
R_{WB}(D) = \frac{D}{256} \times R_{AB} + R_{W}
$$
 (1)

where:

- *D* is the decimal equivalent of the binary code between 0 and 255, which is loaded in the 8-bit RDAC register.
- *RAB* is the nominal end-to-end resistance.
- R_W is the wiper resistance contributed by the on resistance of the internal switch.

Again, if R_{AB} = 10 kΩ and the A Terminal can be either open circuit or tied to W, the following output resistance at R_{W} will be set for the following RDAC latch codes.

Note that in the zero-scale condition, a finite wiper resistance of 60 Ω is present. Care should be taken to limit the current flow between W and B in this state to a maximum current of no more than ±20 mA. Otherwise, degradation or possible destruction of the internal switch contact can occur.

Similar to the mechanical potentiometer, the resistance of the RDAC between Wiper W and Terminal A also produces a digitally controlled resistance, R_{WA} . When these terminals are used, the B Terminal can be opened or tied to the Wiper Terminal. Setting the resistance value for R_{WA} starts at a maximum value of resistance and decreases as the data loaded in the latch increases in value. The general equation for this operation is:

$$
R_{WA}(D) = \frac{256 - D}{256} \times R_{AB} + R_W \tag{2}
$$

For R_{AB} = 10 k Ω , and the B Terminal can be either open circuit or tied to W. The following output resistance *RWA* will be set for the following RDAC latch codes.

The typical distribution of the nominal resistance R_{AB} from channel to channel matches within $\pm 1\%$ for AD5242. Deviceto-device matching is process lot dependent and it is possible to have ±30% variation. Since the resistance element is processed in thin film technology, the change in R_{AB} with temperature has no more than a 30 ppm/°C temperature coefficient.

PROGRAMMING THE POTENTIOMETER DIVIDER Voltage Output Operation

The digital potentiometer easily generates output voltages at wiper-to-B and wiper-to-A to be proportional to the input voltage at A-to-B. Unlike the polarity of $V_{DD} - V_{SS}$, which must be positive, voltage across A–B, W–A, and W–B can be at either polarity provided that V_{SS} is powered by a negative supply.

If ignoring the effect of the wiper resistance for approximation, connecting the A Terminal to 5 V and the B Terminal to ground produces an output voltage at the wiper-to-B starting at 0 V up to 1 LSB less than 5 V. Each LSB of voltage is equal to the voltage applied across Terminal AB divided by the 256 positions of the potentiometer divider. Since AD5241/AD5242 can be supplied by dual supplies, the general equation defining the output voltage at V_W with respect to ground for any valid input voltage applied to Terminals A and B is:

$$
V_W(D) = \frac{D}{256}V_A + \frac{256 - D}{256}V_B
$$
 (3)

which can be simplified to

$$
V_W(D) = \frac{D}{256} V_{AB} + V_B
$$
 (4)

where *D* is the decimal equivalent of the binary code between 0 to 255 that is loaded in the 8-bit RDAC register.

For more accurate calculation including the effects of wiper resistance, V_W can be found as:

$$
V_{W} (D) = \frac{R_{WB} (D)}{R_{AB}} V_{A} + \frac{R_{WA} (D)}{R_{AB}} V_{B}
$$
 (5)

where $R_{WB}(D)$ and $R_{WA}(D)$ can be obtained from Equations 1 and 2.

Operation of the digital potentiometer in the Divider Mode results in a more accurate operation over temperature. Unlike the Rheostat Mode, the output voltage is dependent on the ratio of the internal resistors R_{WA} and R_{WB} , and not the absolute values; therefore, the temperature drift reduces to 5 ppm/°C.

DIGITAL INTERFACE 2-Wire Serial Bus

The AD5241/AD5242 are controlled via an $I²C$ compatible serial bus. The RDACs are connected to this bus as slave devices.

Referring to Figures 2 and 3, the first byte of AD5241/AD5242 is a Slave Address Byte. It has a 7-bit slave address and an R/\overline{W} Bit. The 5 MSBs are 01011 and the following two bits are determined by the state of the AD0 and AD1 Pins of the device. AD0 and AD1 allow users to use up to four of these devices on one bus.

The 2-wire $I²C$ serial bus protocol operates as follows:

1. The master initiates data transfer by establishing a START condition, which is when a high-to-low transition on the SDA line occurs while SCL is high (Figure 2). The following byte is the Slave Address Byte, Frame 1, which consists of the 7-bit slave address followed by an R/\overline{W} Bit (this bit determines whether data will be read from or written to the slave device).

The slave whose address corresponds to the transmitted address will respond by pulling the SDA line low during the ninth clock pulse (this is termed the Acknowledge Bit). At this stage, all other devices on the bus remain idle while the selected device waits for data to be written to or read from its serial register. If the R/\overline{W} Bit is high, the master will read from the slave device. If the R/\overline{W} Bit is low, the master will write to the slave device.

2. A Write operation contains an extra Instruction Byte more than the Read operation. This Instruction Byte, Frame 2, in Write Mode follows the Slave Address Byte. The MSB of the Instruction Byte labeled \overline{A}/B is the RDAC subaddress select. A "low" selects RDAC1 and a "high" selects RDAC2 for the dual-channel AD5242. Set \overline{A}/B to low for AD5241. The second MSB, RS, is the midscale reset. A logic high of this bit moves the wiper of a selected RDAC to the center tap where $R_{WA} = R_{WB}$. The third MSB, SD, is a shutdown bit. A logic high on SD causes the RDAC open circuit at Terminal A while shorting the wiper to Terminal B. This operation yields almost a 0 Ω in Rheostat Mode or 0 V in Potentiometer Mode. This SD Bit serves the same function as the SHDN

Pin except that SHDN Pin reacts to active low. The following two bits are O_2 and O_1 . They are extra programmable logic outputs that users can use to drive other digital loads, logic gates, LED drivers, analog switches, and the like. The three LSBs are Don't Care. See Figure 2.

- 3. After acknowledging the Instruction Byte, the last byte in Write Mode is the Data Byte, Frame 3. Data is transmitted over the serial bus in sequences of nine clock pulses (eight data bits followed by an Acknowledge Bit). The transitions on the SDA line must occur during the low period of SCL and remain stable during the high period of SCL (Figure 2).
- 4. Unlike the Write Mode, the Data Byte follows immediately after the acknowledgment of the Slave Address Byte in Read Mode, Frame 2. Data is transmitted over the serial bus in sequences of nine clock pulses (slightly different than the Write Mode, there are eight data bits followed by a No Acknowledge logic 1 Bit in Read Mode). Similarly, the transitions on the SDA line must occur during the low period of SCL and remain stable during the high period of SCL. See Figure 3.
- 5. When all Data Bits have been read or written, a STOP condition is established by the master. A STOP condition is defined as a low-to-high transition on the SDA line while SCL is high. In Write Mode, the master will pull the SDA line high during the tenth clock pulse to establish a STOP condition (see Figure 2). In Read Mode, the master will issue a No Acknowledge for the ninth clock pulse (i.e., the SDA line remains high). The master will then bring the SDA line low before the tenth clock pulse, which goes high to establish a STOP condition (see Figure 3).

A repeated Write function gives the user flexibility to update the RDAC output a number of times after addressing and instructing the part only once. During the Write cycle, each Data Byte will update the RDAC output. For example, after the RDAC has acknowledged its Slave Address and Instruction Bytes, the RDAC output will be updated. If another byte is written to the RDAC while it is still addressed to a specific slave device with the same instruction, this byte will update the output of the selected slave device. If different instructions are needed, the Write Mode has to start a whole new sequence with a new Slave Address, Instruction, and Data Bytes transferred again. Similarly, a repeated Read function of the RDAC is also allowed.

READBACK RDAC VALUE

Specific to the AD5242 dual-channel device, the channel of interest is the one that was previously selected in the Write Mode. In addition, to read both RDAC values consecutively, users have to perform two write-read cycles. For example, users may first specify the RDAC1 subaddress in the Write Mode (it is not necessary to issue the Data Byte and the STOP condition), then change to the Read Mode and read the RDAC1 value. To continue reading the RDAC2 value, users have to switch back to the Write Mode and specify the subaddress, then switch once again to the Read Mode and read the RDAC2 value. It is not necessary to issue the Write Mode Data Byte or the first stop condition for this operation. Users should refer to Figures 2 and 3 for the programming format.

MULTIPLE DEVICES ON ONE BUS

Figure 5 shows four AD5242 devices on the same serial bus. Each has a different slave address since the state of their AD0 and AD1 Pins are different. This allows each RDAC within

each device to be written to or read from independently. The master device output bus line drivers are open-drain pulldowns in a fully I^2C compatible interface. Note, a device will be addressed properly only if the bit information of AD0 and AD1 in the Slave Address Byte matches with the logic inputs at pins AD0 and AD1 of that particular device.

Figure 5. Multiple AD5242 Devices on One Bus

LEVEL-SHIFT FOR BIDIRECTIONAL INTERFACE

While most old systems may be operated at one voltage, a new component may be optimized at another. When they operate the same signal at two different voltages, a proper method of levelshifting is needed. For instance, one can use a $3.3 \text{V} E^2$ PROM to interface with a 5 V digital potentiometer. A level-shift scheme is needed in order to enable a bidirectional communication so that the setting of the digital potentiometer can be stored to and retrieved from the E^2 PROM. Figure 6 shows one of the techniques. M1 and M2 can be N-Ch FETs 2N7002 or low threshold FDV301N if V_{DD} falls below 2.5 V.

Figure 6. Level-Shift for Different Voltage Devices Operation

Figure 7. Output Stage of Logic Output O_1

ADDITIONAL PROGRAMMABLE LOGIC OUTPUT

AD5241/AD5242 feature additional programmable logic outputs, O_1 and O_2 that can be used to drive digital load, analog switches, and logic gates. They can also be used as self-contained shutdown as preset to logic 0 feature which will be explained later. O_1 and O_2 default to logic 0 during power-up. The logic states of O_1 and O_2 can be programmed in Frame 2 under the Write Mode (see Figure 2). Figure 7 shows the output stage of $O₁$ which employs large P and N channel MOSFETs in push-pull configuration. As shown, the output will be equal to V_{DD} or V_{SS} , and these logic outputs have adequate current driving capability to drive milliamperes of load.

Users can also activate O_1 and O_2 in three different ways without affecting the wiper settings.

- 1. Start, Slave Address Byte, Acknowledge, Instruction Byte with O_1 and O_2 specified, Acknowledge, Stop.
- 2. Complete the write cycle with Stop, then Start, Slave Address Byte, Acknowledge, Instruction Byte with O_1 and O_2 specified, Acknowledge, Stop.
- 3. Do not complete the write cycle by not issuing the Stop, then Start, Slave Address Byte, Acknowledge, Instruction Byte with O_1 and O_2 specified, Acknowledge, Stop.

All digital inputs are protected with a series input resistor and parallel Zener ESD structures shown in Figure 9. This applies to digital input Pins SDA, SCL, and SHDN.

SELF-CONTAINED SHUTDOWN FUNCTION

Shutdown can be activated by strobing the SHDN Pin or programming the SD Bit in the Write Mode Instruction Byte. In addition, shutdown can even be implemented with the device digital output as shown in Figure 8. In this configuration, the device will be shut down during power-up, but users are allowed to program the device. Thus when $O₁$ is programmed high, the device will exit from the shutdown mode and respond to the new setting. This self-contained shutdown function allows absolute shutdown during power-up, which is crucial in hazardous environments without adding extra components.
